Introduction

- NMR is the most powerful tool available for organic structure determination.
- It is used to study a wide variety of nuclei:
 - ^1H
 - ^{13}C
 - ^{15}N
 - ^{19}F
 - ^{31}P

=>

Nuclear Spin

- A nucleus with an odd atomic number or an odd mass number has a nuclear spin.
- The spinning charged nucleus generates a magnetic field.

spinning proton

loop of current

bar magnet

⇒
3

External Magnetic Field

When placed in an external field, spinning protons act like bar magnets.

Copyright © 2005 Pearson Prentice Hall, Inc.

Two Energy States

The magnetic fields of the spinning nuclei will align either *with* the external field, or *against* the field.

A photon with the right amount of energy can be absorbed and cause the spinning proton to flip. =>

Copyright © 2005 Pearson Prentice Hall, Inc.

ΔE and Magnet Strength

- Energy difference is proportional to the magnetic field strength.
- $$\Delta E = h\nu = \frac{\gamma \hbar B_0}{2\pi}$$
- Gyromagnetic ratio, γ , is a constant for each nucleus (26,753 s⁻¹gauss⁻¹ for H).
- In a 14,092 gauss field, a 60 MHz photon is required to flip a proton.
- Low energy, radio frequency. =>

Magnetic Shielding

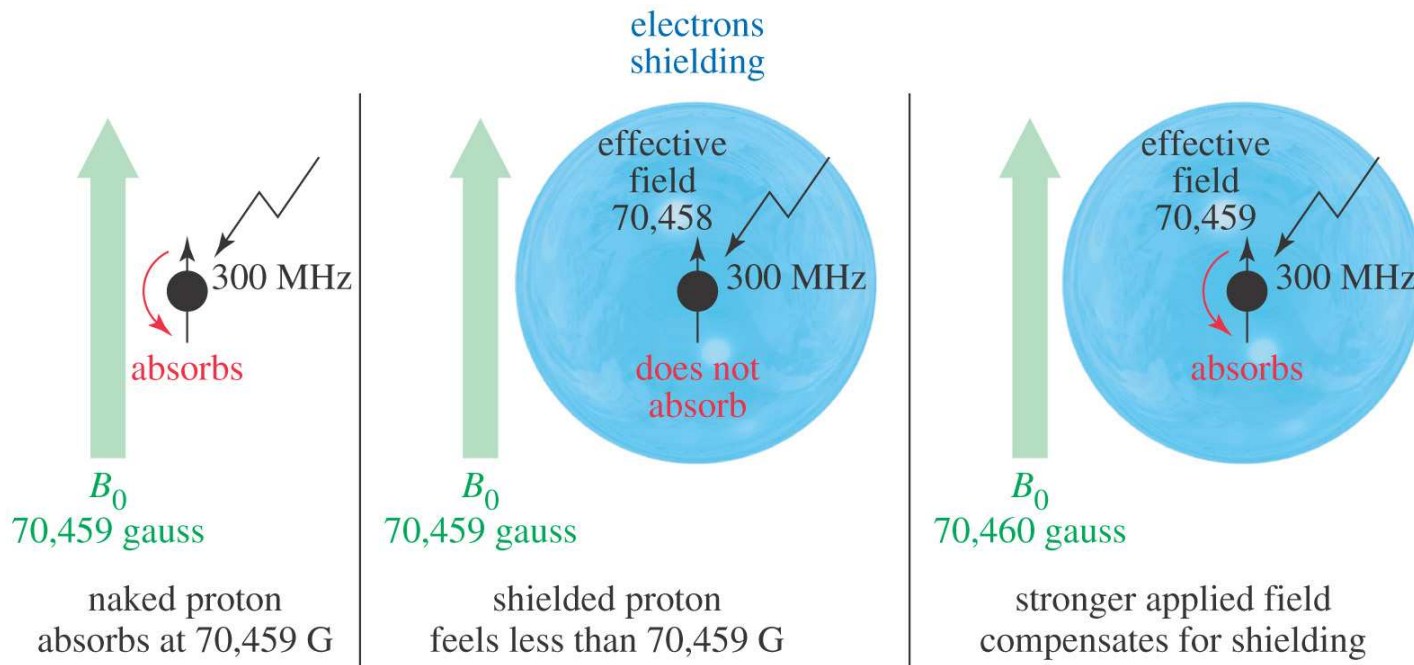

- If all protons absorbed the same amount of energy in a given magnetic field, not much information could be obtained.
 - But protons are surrounded by electrons that shield them from the external field.
 - Circulating electrons create an induced magnetic field that opposes the external magnetic field.
- =>

Shielded Protons

Magnetic field strength must be increased for a shielded proton to flip at the same frequency.

⇒

Protons in a Molecule

Depending on their chemical environment, protons in a molecule are shielded by different amounts.

Copyright © 2005 Pearson Prentice Hall, Inc.

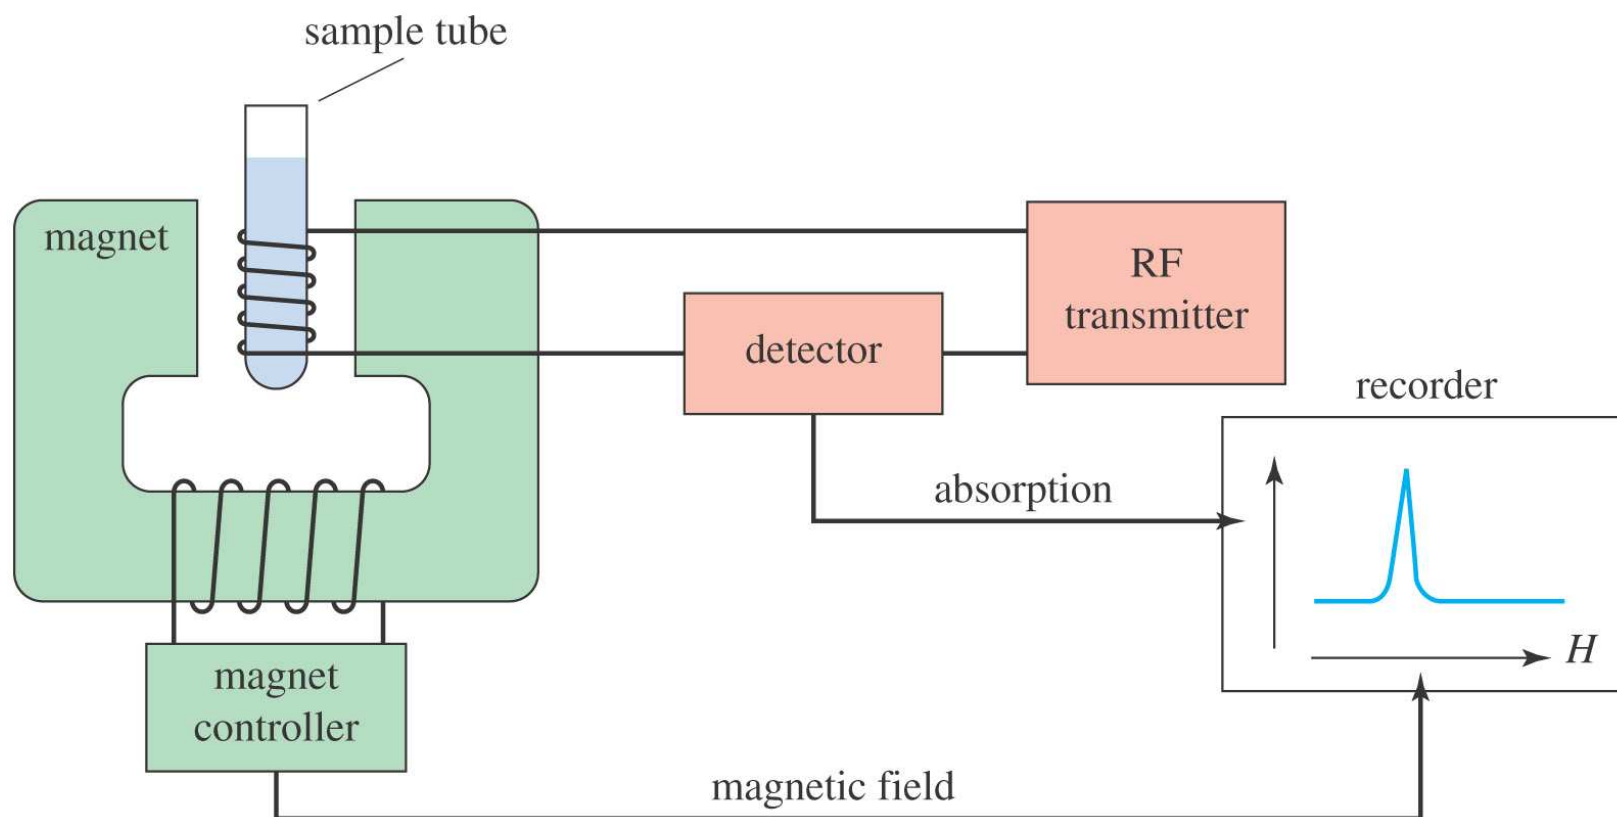

NMR Signals

- The ***number*** of signals shows how many different kinds of protons are present.
- The ***location*** of the signals shows how shielded or deshielded the proton is.
- The ***intensity*** of the signal shows the number of protons of that type.
- Signal ***splitting*** shows the number of protons on adjacent atoms.

Tetramethylsilane

- TMS is added to the sample.
- Since silicon is less electronegative than carbon, TMS protons are highly shielded. Signal defined as zero.
- Organic protons absorb downfield (to the left) of the TMS signal.

=>

Chemical Shift

- Measured in parts per million.
- Ratio of shift downfield from TMS (Hz) to total spectrometer frequency (Hz).
- Same value for 60, 100, or 300 MHz machine.
- Called the delta scale.

=>

Delta Scale

$$\text{chemical shift, ppm } \delta = \frac{\text{shift downfield from TMS (in Hz)}}{\text{spectrometer frequency (in MHz)}}$$

60 MHz

300 MHz

Location of Signals

TABLE 13-2 Chemical Shifts of the Chloromethanes

Compound	Chemical Shift	Difference
$\begin{array}{c} \text{H} \\ \\ \text{H}-\text{C}-\text{H} \\ \\ \text{H} \end{array}$	$\delta 0.2$	
$\begin{array}{c} \text{H} \\ \\ \text{H}-\text{C}-\text{Cl} \\ \\ \text{H} \end{array}$	$\delta 3.0$	2.8 ppm
$\begin{array}{c} \text{H} \\ \\ \text{Cl}-\text{C}-\text{Cl} \\ \\ \text{H} \end{array}$	$\delta 5.3$	2.3 ppm
$\begin{array}{c} \text{H} \\ \\ \text{Cl}-\text{C}-\text{Cl} \\ \\ \text{Cl} \end{array}$	$\delta 7.2$	1.9 ppm

Note: Each chlorine atom added changes the chemical shift of the remaining methyl protons by 2 to 3 ppm. These changes are nearly additive.

Copyright © 2005 Pearson Prentice Hall, Inc.

- More electronegative atoms deshield more and give larger shift values.
- Effect decreases with distance.
- Additional electronegative atoms cause increase in chemical shift.

=>

Typical Values

TABLE 13-3 Typical Values of Chemical Shifts

Type of Proton	Approximate δ	Type of Proton	Approximate δ
alkane ($-\text{CH}_3$)	0.9	>C=C< CH_3	1.7
alkane ($-\text{CH}_2-$)	1.3	Ph—H	7.2
alkane ($-\overset{\text{H}}{\underset{ }{\text{C}}}-$)	1.4	Ph— CH_3	2.3
$\begin{array}{c} \text{O} \\ \\ -\text{C}-\text{CH}_3 \end{array}$	2.1	R—CHO	9–10
$-\text{C}\equiv\text{C}-\text{H}$	2.5	R—COOH	10–12
R— CH_2 —X (X = halogen, O)	3–4	R—OH	variable, about 2–5
$\begin{array}{c} \text{>} \\ \text{C} \\ \text{<} \end{array} = \begin{array}{c} \text{<} \\ \text{C} \\ \text{>} \end{array} - \text{H}$	5–6	Ar—OH	variable, about 4–7
		R— NH_2	variable, about 1.5–4

Note: These values are approximate, as all chemical shifts are affected by neighboring substituents. The numbers given here assume that alkyl groups are the only other substituents present. A more complete table of chemical shifts appears in Appendix 1.

O-H and N-H Signals

- Chemical shift depends on concentration.
- Hydrogen bonding in concentrated solutions deshield the protons, so signal is around $\delta 3.5$ for N-H and $\delta 4.5$ for O-H.
- Proton exchanges between the molecules broaden the peak.

=>

Carboxylic Acid Proton, $\delta 10+$

Number of Signals

Equivalent hydrogens have the same chemical shift.

Copyright © 2005 Pearson Prentice Hall, Inc.

Intensity of Signals

- The area under each peak is proportional to the number of protons.
- Shown by integral trace.

How Many Hydrogens?

When the molecular formula is known, each integral rise can be assigned to a particular number of hydrogens.

Copyright © 2005 Pearson Prentice Hall, Inc.

Spin-Spin Splitting

- Nonequivalent protons on adjacent carbons have magnetic fields that may align with or oppose the external field.
- This magnetic coupling causes the proton to absorb slightly downfield when the external field is reinforced and slightly upfield when the external field is opposed.
- All possibilities exist, so signal is split. =>

1,1,2-Tribromoethane

Nonequivalent protons on adjacent carbons.

Doublet: 1 Adjacent Proton

=>

Triplet: 2 Adjacent Protons

=>

The $N + 1$ Rule

If a signal is split by N equivalent protons, it is split into $N + 1$ peaks.

Relative Peak Intensities of Symmetric Multiplets		
<i>Number of Equivalent Protons Causing Splitting</i>	<i>Number of Peaks (multiplicity)</i>	<i>Area Ratios (Pascal's triangle)</i>
0	1 (singlet)	1
1	2 (doublet)	1 1
2	3 (triplet)	1 2 1
3	4 (quartet)	1 3 3 1
4	5 (quintet)	1 4 6 4 1
5	6 (sextet)	1 5 10 10 5 1
6	7 (septet)	1 6 15 20 15 6 1

Range of Magnetic Coupling

- Equivalent protons do not split each other.
- Protons bonded to the same carbon will split each other only if they are not equivalent.
- Protons on adjacent carbons normally will couple.
- Protons separated by four or more bonds will not couple.

=>

Splitting for Ethyl Groups

Copyright © 2005 Pearson Prentice Hall, Inc.

=>

Splitting for Isopropyl Groups

Copyright © 2005 Pearson Prentice Hall, Inc.

⇒

Coupling Constants

- Distance between the peaks of multiplet
- Measured in Hz
- Not dependent on strength of the external field
- Multiplets with the same coupling constants may come from adjacent groups of protons that split each other.

=>

Values for Coupling Constants

		<u>Approx. J</u>		<u>Approx. J</u>
$\begin{array}{c} & \\ -\text{C} & - & \text{C}- \\ & \\ \text{H} & \text{H} \end{array}$	(free rotation)	7 Hz ^a		8 Hz
$\begin{array}{c} & \diagup & & \diagdown \\ & \text{C}=\text{C} & \\ \diagdown & & \diagup \\ \text{H} & & \text{H} \end{array}$	(cis)	10 Hz		2 Hz
$\begin{array}{c} & \diagup & & \diagdown \\ & \text{C}=\text{C} & \\ \diagdown & & \diagup \\ \text{H} & & \text{H} \end{array}$	(trans)	15 Hz		6 Hz
$\begin{array}{c} & \diagup & \text{H} \\ & \text{C}=\text{C} & \\ & \diagdown & \text{H} \end{array}$	(geminal)	2 Hz		

^aThe value of 7 Hz in an alkyl group is averaged for rapid rotation about the carbon–carbon bond. If rotation is hindered by a ring or bulky groups, other splitting constants may be observed.

Complex Splitting

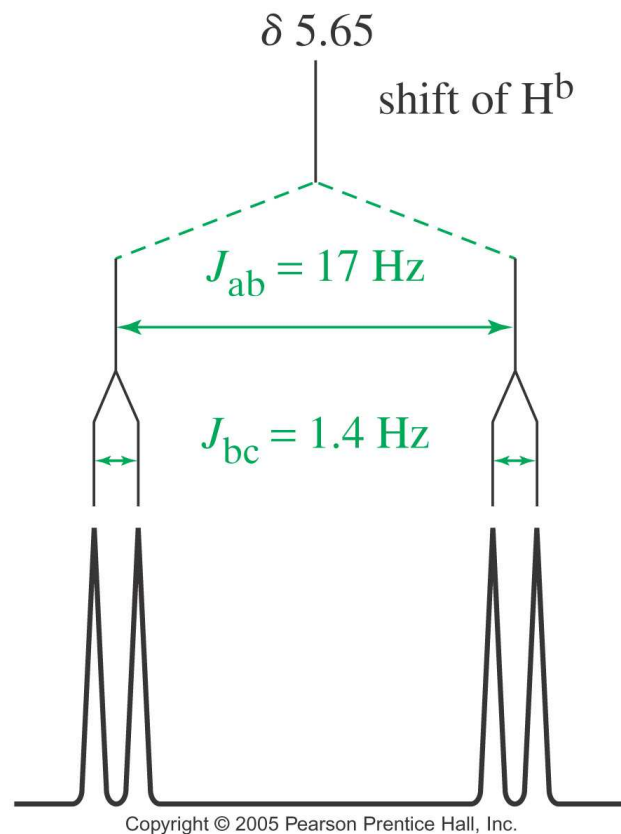

- Signals may be split by adjacent protons, different from each other, with different coupling constants.
- Example: H^a of styrene which is split by an adjacent H *trans* to it ($J = 17$ Hz) and an adjacent H *cis* to it ($J = 11$ Hz).

=>

Splitting Tree

Spectrum for Styrene

Copyright © 2005 Pearson Prentice Hall, Inc.

=>

Stereochemical Nonequivalence

- Usually, two protons on the same C are equivalent and do not split each other.
- If the replacement of each of the protons of a $-\text{CH}_2$ group with an imaginary “Z” gives stereoisomers, then the protons are non-equivalent and will split each other.

=>

Some Nonequivalent Protons

Time Dependence

- Molecules are tumbling relative to the magnetic field, so NMR is an averaged spectrum of all the orientations.
- Axial and equatorial protons on cyclohexane interconvert so rapidly that they give a single signal.
- Proton transfers for OH and NH may occur so quickly that the proton is not split by adjacent protons in the molecule.

Hydroxyl Proton

- Ultrapure samples of ethanol show splitting.
- Ethanol with a small amount of acidic or basic impurities will not show splitting.

N-H Proton

- Moderate rate of exchange.
- Peak may be broad.

Copyright © 2005 Pearson Prentice Hall, Inc.

=>

Identifying the O-H or N-H Peak

- Chemical shift will depend on concentration and solvent.
- To verify that a particular peak is due to O-H or N-H, shake the sample with D_2O .
- Deuterium will exchange with the O-H or N-H protons.
- On a second NMR spectrum the peak will be absent, or much less intense.

Carbon-13

- ^{12}C has no magnetic spin.
- ^{13}C has a magnetic spin, but is only 1% of the carbon in a sample.
- The gyromagnetic ratio of ^{13}C is one-fourth of that of ^1H .
- Signals are weak, getting lost in noise.
- Hundreds of spectra are taken, averaged.

=>

Fourier Transform NMR

- Radio-frequency pulse given.
 - Nuclei absorb energy and precess (spin) like little tops.
 - A complex signal is produced, then decays as the nuclei lose energy.
 - Free induction decay is converted to spectrum.
- =>

Hydrogen and Carbon Chemical Shifts

-COOH
 $\delta 11-12$

X = O, hal

Combined ^{13}C and ^1H Spectra

Differences in ^{13}C Technique

- Resonance frequency is \sim one-fourth, 15.1 MHz instead of 60 MHz.
- Peak areas are not proportional to number of carbons.
- Carbon atoms with more hydrogens absorb more strongly.

\Rightarrow

Spin-Spin Splitting

- It is unlikely that a ^{13}C would be adjacent to another ^{13}C , so splitting by carbon is negligible.
- ^{13}C will magnetically couple with attached protons and adjacent protons.
- These complex splitting patterns are difficult to interpret.

=>

Proton Spin Decoupling

- To simplify the spectrum, protons are continuously irradiated with “noise,” so they are rapidly flipping.
- The carbon nuclei see an average of all the possible proton spin states.
- Thus, each different kind of carbon gives a single, unsplit peak.

=>

Off-Resonance Decoupling

- ^{13}C nuclei are split only by the protons attached directly to them.
- The $N + 1$ rule applies: a carbon with N number of protons gives a signal with $N + 1$ peaks.

=>

Interpreting ^{13}C NMR

- The number of different signals indicates the number of different kinds of carbon.
- The location (chemical shift) indicates the type of functional group.
- The peak area indicates the numbers of carbons (if integrated). – **Not always true.**
- The splitting pattern of off-resonance decoupled spectrum indicates the number of protons attached to the carbon. =>

Two ^{13}C NMR Spectra (coupled to hydrogen and decoupled)

MRI

- Magnetic resonance imaging, noninvasive
- “Nuclear” was omitted because of public’s fear that it would be radioactive.
- Only protons in one plane can be in resonance at one time.
- Computer puts together “slices” to get 3D.
- Tumors readily detected.
